#### Abstract

Motivation. Bisphosphonates (BPs) are most widely used as agents for treating osteoporosis due to their inhibitory activity. They have also been used for other purposes such as herbicides, anticancer agents, and antiparasitics. Here we report QSAR models of four BPs datasets based on the 118 structural and biological data we have collected from various literature sources.

Method. Based on the descriptors provided by molecular operating environment (MOE), the step by step multiple regression and principle analysis were used to achieve our QSAR models. Results. The QSAR model for a dataset of 28 GGPPSase inhibitors is made up of two descriptors with its $\mathrm{R}^{2}$ 0.86 and leave-one-out cross-validated $\mathrm{R}^{2} 0.82$. Another dataset of 28 compounds with bioactivities against the growth of T. Brucei rhodesiense was studied using PCA and reached a model with $\mathrm{R}^{2} 0.85$ and leave-one-out cross-validated $\mathrm{R}^{2}$ around 0.80 . Both the above models have comparable predictive ability with CoMFA model reported by Szabo et al. The 86 BPs provided by Novartis with in vivo bio-data of TPTX rats were divided into two datasets. A six-variable PCA model elucidated the dataset of 44 compounds in which containing aliphatic linked nitrogen atoms. Its $\mathrm{R}^{2}$ is 0.80 and leave-one-out cross-validated $\mathrm{R}^{2} 0.72$. The other dataset includes 42 BPs containing a heterocyclic moiety with at least one nitrogen atom. Its PCA model with $\mathrm{R}^{2} 0.80$ and leave-one-out cross-validated $\mathrm{R}^{2} 0.71$ consists of seven PCA variables. Conclusions. A leave-four-out test procedure shows that though the QSAR models based on in vivo bone resorption $\mathrm{pED}_{50}$ values cannot provide explicit indications for drug design, their predictive ability for related compounds is quite good..

Keywords. Bisphosphonate; principal component analysis (PCA); GGPPSase inhibitor; quantitative structureactivity relationships (QSAR); $\mathrm{IC}_{50} ; \mathrm{ED}_{50}$

## 1 INTRODUCTION

Bisphosphonates (BPs) are the most widely used inhibitors of bone resorption. They all contain

[^1]two phosphonate groups attached to a single carbon atom, forming a "P-C-P" structure. Bisphosphonates are stable analogs of naturally occurring pyrophosphate-containing compounds, which now helps to explain their intracellular as well as their extracelluar modes of action. Several bisphosphonates, e.g., etidronate, clodronate, pamidronate, alendronate, tiludronate, risedronate, and ibandronate, have been established as effective treatments in clinical disorders such as Paget's disease of bone, tumour-associated bone disease, and osteoporosis [1]. Bisphosphonates have also been repeated for uses as herbcides [2], anticancer agents [3], and antiparasitics [4,5].

Recent studies suggest that bisphosphonates inhibit bone resorption by cellular effects on boneresorbing osteoclasts, rather than by purely physicochemical mechanisms. It is likely that BPs are internalized by osteoclasts and interfere with specific biochemical process and induce apoptosis ${ }^{6}$. In recent work, the site of action has been narrowed down to the mevalonate pathway and the isoprene pathway. The exact enzymes of the mevalonate pathway that are inhibited by BPs have not yet been fully identified. However, incadronate and ibandronate are known inhibitors of squalene synthase, an enzyme in the mevalonate pathway required for cholesterol biosynthesis [6]. Alendronate and pamidronate are less potent inhibitors of squalene synthase but can also inhibit sterol biosynthesis, suggesting that these bisphosphonates may inhibit up stream enzymes of the mevalonate pathway other than squalene synthase [7].

Several enzymes of the mevalonate pathway such as isoprenoid diphosphate isomerase (IPP isomerase), farnesyl diphosphate synthase (FPPSase), geranylgeranyl diphosphate synthase (GGPPSase), and squalene synthase, utilize an isoprenoid diphosphate as a substrate and thus are likely to have similar substrate binding sites. Thus if nitrogen-containing BPs act as substrate analogs of an isoprenoid diphosphate, it is likely that these BPs actually inhibit several enzymes of the mevalonate pathway. FPPSase are the most reported target for many BPs. For example, Cromartie and Fisher demonstrated that herbicidal bisphosphonates were potent, low-nanomolar inhibitors of a daffodil FPPSase [2,8], and Grove et al. reported that BPs were growth and FPPSase inhibitors of the primitive eukaryote Dictyostelium discoideum [9]. Several groups [1,3,10,11] have reported that FPPSase was the target of the nitrogen-containing bisphosphonates in bone, leading to the apoptosis of osteoclasts. The group of Eric Oldfield, which did a lot of jobs on chemotherapy of parasitic protozoa diseases, reported that bisphosphonates were in vitro inhibitors of the growth of the causative agents of Chagas' disease, human East African trypanosomiasis, visceral leishmaniasis, toxoplasmosis, malaria, and cryptosporidiosis, T. Cruzi, Trypanosoma brucei rhodesiense Leishmania donovani, Toxoplasma gondii, Plasmodium falciparum, and Cryptosporidium parvum [4,5]. They also showed that in some of the parasites, such as T. b. rhodesiense and $D$. discoideum, the molecular target of some bisphosphonates such as risedronate is FPPSase and reported 3D-QSAR/CoMFA investigation of bisphosphonate drugs, in the inhibition of bone resorption as well as the growth of $D$. discoideum and the bloodstream form of $T . b$. rhodesiense [5,12]. Though there are fewer reports, other enzymes, e.g. IPP isomerase, GGPP
synthase, and squalene synthase of the mevalonate pathway, may be also potential targets for different bisphosphonates.

Eric Oldfield group has investigated the inhibition of a human recombinant GGPPSase by 23 bisphosphonates and six azaptenyl diphosphates. In addition to CoMFA analysis of structureactivity relationship, the pharmacophore of these GGPPSase inhibitors obtained from Catalyst was also provided [13].

Though the actual conformations of the bisphosphonates in the FPPSase and GGPPSase active sites are not yet known, good predictive CoMFA models were obtained using the molecular mechanics-derived lowest-energy conformers [5,12,13].

Widler et al. reported an extensive structure-activity relationship (SAR) study of bisphosphonates [14]. Small changes of the structure of pamidronate (2 compound) lead to marked improvements of the inhibition of osteoclastic resorption potency. Alendronate (compound 3 in Table 1), with an extra methylene group in the N -alkyl chain, and olpadronate (compound 7), the N , N -dimethyl analogue, are about 10 times more potent than pamidronate (compound 2). Extending one of the N-methyl groups of olpadronate to a pentyl substituent leads to ibandronate (compound 10), which is the most potent close analogue of pamidronate. Even slightly better antiresorptive potency is achieved with derivatives having a phenyl group linked via a short aliphatic tether of three to four atoms to nitrogen, the second substituent being preferentially a methyl group. The most potent bisphosphonate, zoledronate (compound 65), is found in the series containing a heteroaromatic moiety with at least one nitrogen atom, which is linked via a single methylene group to the geminal bisphosphonate unit [14].

The comprehension of BPs mechanism gives us indications to investigate the quantitative structure-activity relationship of the bisphosphonates provided by Novartis [14] with in vivo $\mathrm{ED}_{50}$ against hypercalcemia induced in thyroparathyroidectomy (TPTX) rats. The total of 86 compounds were divided into two datasets, one for the series containing a heterocyclic moiety, which contains at least one nitrogen atom; the other for bisphosphonates that contains a nitrogen atom in aliphatic link and do not possess a heterocyclic substitute. The two datasets were analyzed using QSAR module of MOE and achieved two predictive models through principal component analysis.

We also investigated the BPs with $\mathrm{IC}_{50}$ against T. Brucei Trypomastigotes $[4,5]$ and BPs with $\mathrm{IC}_{50}$ for GGPPSase inhibition [13] using the molecular modeling package MOE respectively, and achieved more simple and lightening models.

## 2 MATERIALS AND METHODS

### 2.1 Chemical Data

The structures we have collected here are listed in the Table 1 along with compound code and bioactivities. Some of the compound codes were assigned following their traditional name such as 'alendronate' and 'pamidronate', or codes from original references such as 'NE58018' and 'NE97220'. The others were assigned according original activity source such as 'T.B.006' and 'GGPP031', or data provider such as 'Novartis1a' and 'Novartis1d'.

[^2]or nitrogen-free side chains, together with different location of the side chain nitrogens. The $\mathrm{pIC}_{50}$ values of this dataset vary from 3.16 to 6.85 ; with a mean value of 4.49 and a SD of 1.23 . The distribution of activity of this dataset is shown in Figure 1.

FIGURE 1. $\mathrm{pIC}_{50}$ distribution of dataset1
Dataset 2 include 28 bisphosphonates and their $\mathrm{IC}_{50}$ values against the growth of T. Brucei rhodesiense that is one of the causative agents of human African trypanosomiasis (sleeping sickness) ${ }^{5}$. The FPPSase is considered at least the main target of nitrogen-containing bisphosphonates in T. Brucei rhodesiense ${ }^{4,5}$. The $\mathrm{pIC}_{50}$ values of this dataset vary from 3.75 to 6.66; with a mean value of 4.91 and a SD of 0.79 . The distribution of activity of this dataset is shown in Figure 2.

FIGURE 2. $\mathrm{pIC}_{50}$ distribution of dataset2
The structures and activity data of dataset 3 and dataset 4 are both from Novartis pharma research ${ }^{14}$. The $\mathrm{ED}_{50}$ values in the two datasets are the doses of compound administratered sc, which results in a $50 \%$ reduction of the hypercalcemia induced in TPTX rats by 1,25-dihydroxyvitamin $\mathrm{D}_{3}$.

We have known from the Introduction that the in vivo effect of bisphosphonates involves several enzymes of the mevalonate pathway e.g. IPP isomerase, FPP synthase, GGPP synthase, and squalene synthase. Therefore, the total of 86 compounds from Novartis were divided into two datasets according their structural features and rough speculation on their mode of action.

Dataset3 includes 44 bisphosphonates that contain a nitrogen atom in aliphatic link and do not possess nitrogen-containing heterocyclic substitutes. These compounds are less potent inhibitors of FPPSase and are speculated to act mainly with GGPPSase. The $\mathrm{pED}_{50}$ values of this dataset vary from 5.12 to 9.48 , with a mean value of 8.13 and a SD of 0.98 . The distribution of activity of this dataset is shown in Figure 3.

FIGURE3. $\mathrm{pED}_{50}$ distributions of dataset3
Dataset4 includes 42 bisphosphonates containing a heterocyclic moiety, which contains at least one nitrogen atom. Some of these BPs are more potent antiresorptive agents in the in vivo experiment and more potent FPPSase inhibitors in vitro. The $\mathrm{pED}_{50}$ values of this dataset vary from 5.60 to 10.16 ; with a mean value of 7.66 and a SD of 1.06 . The distribution of activity of this dataset is shown in Figure 4.

The $\mathrm{IC}_{50}$ or $\mathrm{ED}_{50}$ values and the respective negative logarithm $\left(\mathrm{pIC}_{50}\right.$ or $\left.\mathrm{pED}_{50}\right)$ for all compounds are listed in the tables of supplementary materials along with model predictions. The stronger inhibitor a compound is, the greater the $\mathrm{pIC}_{50}$ or $\mathrm{pED}_{50}$ is.

### 2.2 Computational Methods and Software Packages

The QSAR modeling process consists of the following steps: structure optimization using MMFF94 force field; selection and evaluation of chemical structure descriptors; descriptor pruning through QSAR-contingency, correlation analysis of descriptors, step-forward and step-backward selection; structural diversity analysis of the dataset based on pruned descriptor set and assigned weight to molecules if necessary; multiple regression analysis between $\mathrm{pIC}_{50}$ and selected descriptors; evaluation of the significance level of the model and each determined descriptor; validation and cross-validation (leave-one-out procedure) of the model; detection of outliers and modifiation of QSAR-model; interpretation of the model equation.

The structures and biological activity data were stored in an ISIS/Base database from which an SD file was exported. The SD file was imported into a molecular modeling package for subsequent calculations. The molecular structures were optimized using MMFF94 force field. All the 181 2D and inner 3D descriptors available in MOE [15] were calculated for every molecule. The QuaSARContingency module was used to prune the descriptors in order to select an optimum subset for

QSAR. The Qua-cluster module of MOE was used to evaluate the diversity of the collection of our molecules based on the table of selected molecular descriptors and assigned weights to molecules if necessary. JMP4.5 (SAS Institute) [16] was used to perform most of the statistical analyses reported in this study.

MOE detects outliers with Grubb's test. The first step is to quantify how far away the experimental $\mathrm{pIC}_{50}$ is from the model value, by calculating the ratio Z -SCORE, defined as the difference between the $\mathrm{pIC}_{50}$ and model value divided by the SD of the whole dataset. MOE provides Z-SCORE values for all molecules and considers molecules with a Z-SCORE of 2.5 or more to be possible outliers. Grubbs and others have tabulated critical values for Z-SCORE which are tabulated below for $\mathrm{p}=0.05 / 0.02$ (two tail) [17]. The critical value increases with sample size. Thus instead of simply taking the MOE criteria of outlier detection, we consulted the Grubb's table of Z-SCORE for different sample sizes for detecting outliers, and considered the complex influence of the PCA method, take the values of $\mathrm{p}=0.02$ as criteria.

Model adequacy was measured as the square of correlation coefficient $\left(R^{2}\right)$, root mean square error (RMSE), cross-validated $\mathrm{R}^{2}\left(\mathrm{XR}^{2}\right)$ and cross-validated RMSE (XRMSE).

## 3 RESULTS AND DISCUSSION

### 3.1 QSAR Model for dataset1

After structure optimization, 181 descriptors were selected and evaluated from MOE descriptor selection panel. After descriptor pruning procedures, 2 descriptors were selected to build the final QSAR model for the data set. ASA denotes the water accessible area calculated using a radius of 1.4Á for the water molecule, while PEOE_VSA-1 denotes the sum of van der Waals surface areas of the atoms whose PEOE partial charge is in the range of [-0.10, -0.05]. PEOE (Partial Equalization of Orbital Electronegativities) [18] method of calculating atomic partial charges is a method in which charge is transferred between bonded atoms until equilibrium. Diversity analysis based on the two descriptors showed that there was no need to assign weight to the molecules. The two-descriptor linear model is shown in equation (1):

$$
\begin{align*}
& \mathrm{pIC}_{50}=0.51396+0.00675 *(\mathrm{ASA})+0.01742 *(\text { PEOE_VSA- } 1)  \tag{1}\\
& \mathrm{R}^{2}=0.86, \mathrm{RMSE}=0.45, \mathrm{XR}^{2}=0.82, \mathrm{XRMSE}=0.51, \mathrm{n}=28 \mathrm{~F}=77.56, \mathrm{~N}=2 .
\end{align*}
$$

ASA and PEOE_VSA- 1 are all positively correlated with $\mathrm{pIC}_{50}$ values, thus increasing ASA and PEOE_VSA-1 will lead to the improvement of $\mathrm{pIC}_{50}$. The parameter effect tests for the model show that ASA is the determined descriptor in the model (Table 2). The 3D-QSAR/CoMFA analysis carried out by Szabo et al. [13] indicates that van der Waals interactions are very important in GGPPSase inhibition. Our model revealed the importance of water accessible surface area, which is
mainly responsible for the van der Waals interactions between BPs and GGPPSase enzyme. Though our model did not provide 3D information like the CoMFA model, it offers a much simple equation and fast method to gain insight into the GGPPSase inhibitor system.

Table 2. Effect tests of the descriptors for model (1)

| Descriptor | Correlation to $\mathrm{pIC}_{50}\left(\mathrm{R}^{2}\right)$ | Sum of Squares | F Ratio | Prob $>\mathrm{F}$ |
| :--- | :--- | :--- | :--- | :--- |
| ASA | 0.76 | 14.61 | 64.78 | $<0.0001$ |
| PEOE_VSA-1 | 0.50 | 4.18 | 18.53 | 0.0002 |

The leave-one-out cross-validated predictive $\mathrm{pIC}_{50}$ values (XPRED) were listed in Table 1 of supplementary material and plotted in Figure 5.

FIGURE 5. Leave-one-out cross-validated prediction versus experimental $\mathrm{pIC}_{50}$ values for dataset 1
To test the predictive ability of our model, we also removed three compounds from the training set and performed the whole QSAR procedure on the reduced training set; then using the resulting model to predict the activities of the three excluded compounds. This procedure was repeated three times using different test sets, and the predicted $\mathrm{pIC}_{50}$ values are listed in bold in Table 1 of supplementary material along with individual training sets and all statistical data for QSAR equations. The three compounds in each test set were chosen following the reference 13 in order to compare the model predictive ability with that of the CoMFA model performed by Szabo et al.. The graphical result of the total nine compounds test set is shown in Figure 6. The root mean square error in predicted $\mathrm{pIC}_{50}$ of the test set compounds is 0.44 , the correlation coefficient between experimental and predicted values is $\mathrm{R}^{2}=0.80$.

FIGURE 6. Predicted $\mathrm{pIC}_{50}$ values versus experimental $\mathrm{pIC}_{50}$ values for 9 GGPPSase inhibitors test set

The QSAR equations for the three training sets with reduced size are as follows:

$$
\begin{align*}
& \mathrm{pIC}_{50}=0.5489+0.006720 *(\mathrm{ASA})+0.01747 *(\text { PEOE_VSA- } 1)  \tag{2}\\
& \mathrm{R}^{2}=0.85, \mathrm{RMSE}=0.47, \mathrm{XR}^{2}=0.81, \mathrm{XRMSE}=0.54, \mathrm{n}=25, \mathrm{~F}=64.53, \mathrm{~N}=2 . \\
& \mathrm{pIC}_{50}=0.8793+0.005812 *(\mathrm{ASA})+0.02083 *(\text { PEOE_VSA-1 })  \tag{3}\\
& \mathrm{R}^{2}=0.88, \mathrm{RMSE}=0.40, \mathrm{XR}^{2}=0.85, \mathrm{XRMSE}=0.46, \mathrm{n}=25, \mathrm{~F}=83.83, \mathrm{~N}=2 . \\
& \mathrm{pIC}_{50}=0.4741+0.006827 *(\mathrm{ASA})+0.01726 *(\text { PEOE_VSA-1 })  \tag{4}\\
& \mathrm{R}^{2}=0.85, \mathrm{RMSE}=0.46, \mathrm{XR}^{2}=0.81, \mathrm{XRMSE}=0.54, \mathrm{n}=25, \mathrm{~F}=64.81, \mathrm{~N}=2 .
\end{align*}
$$

The comparison of model (1) and the CoMFA model reported by Szabo et al. of the dataset1 is listed in Table 3. The RMSE value between predicted and experimental values of the test set (Test RMSE) is 0.39 for the CoMFA model and 0.44 for Model (1). Then, to compare the predictive ability of the two models, we can calculate the $\mathrm{F}_{9,9}=1.27$ from the RMSE values and look up the $\mathrm{F}_{0.05 ; 9,9}=3.18$ from the F distribution. The result of the F test tells us the predictive ability of the two models has no significant difference at $\alpha=0.05$.

| Table 3. Statistical comparison of model (1) from the current study and CoMFA model reported by Szabo et al. ${ }^{13}$ |  |  |  |  |  |  |  |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| Model | $\mathrm{R}^{2}$ | $\mathrm{XR}^{2}$ | $\mathrm{n}^{\mathrm{a}}$ | $\mathrm{N}^{\mathrm{b}}$ | F | Test RMSE | Test R $^{2}$ |
| CoMFA | 0.938 | 0.90 | 28 | 4 | 86.8 | 0.39 | 0.88 |
| Model (1) | 0.86 | 0.82 | 28 | 2 | 77.56 | 0.44 | 0.80 |

$a$ : number of observations. $b$ : number of descriptors for certain model.

### 3.2 QSAR Model for Dataset2

Firstly, the QSAR-contingency, correlation analysis, step-forward and step-backward selection procedures recommended 11 descriptors for the model of dataset2:

$$
\begin{aligned}
& \mathrm{pIC}_{50}=1.01914+1.18053 *\left(\mathrm{a} \_\mathrm{nH}\right)+0.19768 *(\text { Zagreb })-0.04650 *(\text { PEOE_VSA }+1)- \\
& 0.04636 *(\text { PEOE_VSA-1 })-0.02466 *(\mathrm{Q} \text { VSA_PPOS })-0.02865 *(\mathrm{E} \text { sol })+0.29037 *\left(\mathrm{E} \_ \text {stb }\right)+ \\
& 0.55278 *(\text { KierFlex })-0.96729 *(\text { apol })+0.07657 *(\text { vsa_other })+0.08153 *(\text { SlogP_VSA7 }) \\
& \mathrm{R}^{2}=0.89, \text { RMSE }=0.25, \mathrm{XR}^{2}=0.77, \text { XRMSE }=0.37, \mathrm{n}=28, \mathrm{~F}=11.58, \mathrm{~N}=11 .
\end{aligned}
$$

Some of the descriptors such as a_nH, apol, and KierFlex are correlated with (coefficient>0.8) and unreplaceable by each other in the model. So many descriptors make the model complicated and difficult to interpret. And a model of 11 descriptors for a 28 -observation dataset is sure overfitting. In order to obtain a more robust and concise model, we performed principal components analysis (PCA) to reduce the dimensions of the descriptor subset, but failed.

We tried to select another subset among 181 descriptors. The element of the subset was measured mainly by its contribution to $R^{2}$ and $X R^{2}$. Finally we obtained a 32 -descriptor subset, which keeps most interpretive information for $\mathrm{pIC}_{50}$ and have the fewest number of descriptors at the same time. The statistical parameters of the model based on the 32 descriptors are: $\mathrm{R}^{2}=1.00$,

RMSE $=0.00, \mathrm{XR}^{2}=0.80, \mathrm{XRMSE}=0.38$. The names of the 32 descriptors are listed in Table 5 of supplementary materials.

Then we transformed the 32 descriptors into a set of uncorrelated and normalized variables using PCA. To capture $100 \%$ of the variance in the previous 32 -descriptor subset, 26 principal components (PCs) are needed. The accumulative percentage of variance explained by the first five PCs is $81.38 \%$; with the $1^{\text {st }} \mathrm{PC}$ explaining $34.87 \%$, the $2^{\text {nd }} 16.23 \%$, $3^{\text {rd }} 13.22 \%, 4^{\text {th }} 6.01 \%$, and $5^{\text {th }}$ 5.05\%.

After stepwise selection, four PCs (PC2, PC3, PC4, PC5) were determined to best describe the tendency of $\mathrm{pIC}_{50}$. We obtained the following linear model:

$$
\begin{align*}
& \mathrm{pIC}_{50}=4.9108+0.2218 * \mathrm{PC} 2-0.4067 * \mathrm{PC} 3-0.5010 * \mathrm{PC} 4+0.1535 * \mathrm{PC} 5  \tag{6}\\
& \mathrm{R}^{2}=0.85, \mathrm{RMSE}=0.30, \mathrm{XR}^{2}=0.79, \mathrm{XRMSE}=0.35, \mathrm{n}=28, \mathrm{~F}=32.03, \mathrm{~N}=4 .
\end{align*}
$$

The leave-one-out cross-validated predictive $\mathrm{pIC}_{50}$ values were listed in Table 2 of the supplementary materials and plotted in Figure 7.

FIGURE 7. Leave-one-out cross-validated prediction versus experimental $\mathrm{pIC}_{50}$ values for dataset2
We then carried out the leave-three-out procedure just as we did on model (1) from dataset1 model to test whether the PCA model have predictive value. The selection of test compounds followed Martin et al. on the CoMFA model. ${ }^{5}$ The results for three training-test sets of calculations are given in Table 2 of supplementary materials. The graphical representation of the results is shown in Figure 8. The RMSE for the test set compounds was 0.66 , and the correlation coefficient between experimental and predicted $\mathrm{pIC}_{50}$ values was $\mathrm{R}^{2}=0.70$. The results indicate that the PCA model predicts the test set quite well and is not over fitting for the training set.

The comparison of PCA model (6) and the CoMFA model of the dataset2 [5] is listed in Table 4. The RMSE value of the test set (Test RMSE) is 0.32 for CoMFA and 0.66 for Model (6). Then, $\mathrm{F}_{9,9}$ $=4.25$ is larger than the boundary value $\mathrm{F}_{0.05 ; 9,9}=3.18$. It seems that model (6) is inferior to CoMFA model in predictive ability. However, compared to $R^{2}$ and $X R^{2}$, Test $R^{2}$ value for the CoMFA model seems artificially high. General trend should be Test $\mathrm{R}^{2}<\mathrm{XR}^{2}<\mathrm{R}^{2}$ according statistical principle. This may be resulted from chance correlation of the test compounds to the CoMFA
model. Therefore we cannot claim that predictive ability of the two models has significant difference at $\alpha=0.05$.

FIGURE 8. Predicted $\mathrm{pIC}_{50}$ values versus experimental $\mathrm{pIC}_{50}$ values for 9-compound test set of dataset2
Table4. Statistical comparison of model (6) and CoMFA model

| Model | $\mathrm{R}^{2}$ | $\mathrm{XR}^{2}$ | $\mathrm{n}^{\mathrm{a}}$ | $\mathrm{N}^{\mathrm{b}}$ | F | Test RMSE | Test R ${ }^{2}$ |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| CoMFA | 0.87 | 0.79 | 26 | 4 | 34.80 | 0.32 | 0.87 |
| Model (5) | 0.85 | 0.79 | 28 | 4 | 32.03 | 0.66 | 0.70 |

$a$ : number of observations. $b$ : number of descriptors for certain model.
Note: Dataset2 includes pamidronate (compound 2) and T.B.2-13 (compound 118) from reference 4, which did not include in CoMFA dataset. ${ }^{5}$

### 3.3 QSAR model of dataset3

The biological complexity of dataset 3 is much greater than those of dataset 1 and dataset2. The normal descriptor selection procedure suggested 16 descriptors for the dataset, and the statistical parameters of the model based on the 16 descriptors are: $\mathrm{R}^{2}=0.84, \mathrm{RMSE}=0.40, \mathrm{XR}^{2}=0.50$, XRMSE $=0.85, \mathrm{n}=44, \mathrm{~F}=8.36, \mathrm{~N}=16$. The names of the 16 descriptors are listed in Table 5 of supporting materials. Principal component analysis was carried out on the 16 descriptors. 16 PCs are required to capture the $100 \%$ variance in the previous descriptor subset. The accumulative percentage of variance explained by the first five PCs is $91.06 \%$; with the $1^{\text {st }} \mathrm{PC}$ explaining $62.48 \%$, the $2^{\text {nd }} 10.29 \%, 3^{\text {rd }} 8.27 \%, 4^{\text {th }} 5.56 \%$, and $5^{\text {th }} 4.47 \%$. After stepwise selection, six PCs (PC2, PC6, PC9, PC12, PC14, PC15) were selected to build the final model:

$$
\begin{equation*}
\text { pED50 }=8.10-0.35 * \mathrm{PC} 2-0.25 * \mathrm{PC} 6+0.23 * \mathrm{PC} 9-0.65 * \mathrm{PC} 12+0.22 * \mathrm{PC} 14-0.26 * \tag{7}
\end{equation*}
$$ PC15

$$
\mathrm{R}^{2}=0.80, \mathrm{RMSE}=0.44 ; \mathrm{XR}^{2}=0.72, \mathrm{XRMSE}=0.53, \mathrm{n}=44, \mathrm{~F}=24.83, \mathrm{~N}=6
$$

The percentage of variance explained by the 6 descriptors was listed in Table 5 respectively along with the result of parameter effect test of model (7). The most correlative PC of the model (7) is PC12 ( $\mathrm{F}=80.98$ ), which only explains $0.12 \%$ variance of original descriptor subset. The PCA procedure succeeded in extracting useful information and getting rid of noisy information from original dataset.

Table 5. Effect tests of the descriptors for model (7)

| Source | Correlation to $\mathrm{pED}_{50}\left(\mathrm{R}^{2}\right)$ | Sum of Squares | F Ratio | Prob $>\mathrm{F}$ | Percentage of variance (\%) |
| :--- | :---: | :---: | :---: | :---: | :---: |
| PCA12 | 0.44 | 18.76 | 80.98 | $<.0001$ | 0.12 |
| PCA2 | 0.13 | 5.42 | 23.39 | $<.0001$ | 10.29 |
| PCA15 | 0.07 | 3.09 | 13.33 | 0.0008 | 0.01 |
| PCA6 | 0.07 | 2.81 | 12.13 | 0.0013 | 3.56 |
| PCA9 | 0.05 | 2.33 | 10.07 | 0.0030 | 1.31 |
| PCA14 | 0.05 | 2.12 | 9.13 | 0.0045 | 0.02 |

The leave-one-out cross-validated predictive $\mathrm{pIC}_{50}$ values were listed in the Table 3 of supplementary materials and plotted in Figure 9.

FIGURE 9. Leave-one-out cross-validated prediction versus experimental $\mathrm{pED}_{50}$ values for dataset3
To further investigate the predictive ability of this model, we removed four compounds from the training set randomly before recomputing the QSAR equation on the reduced dataset. The $\mathrm{pED}_{50}$ values of the removed compounds were predicted using the QSAR model derived from the reduced training set. The procedure was repeated four times and the predicted $16 \mathrm{pED}_{50}$ values are given in the Table 3 of supplementary materials in bold. The graphical representation of the results is shown in Figure 10. The RMSE between predicted $\mathrm{pED}_{50}$ and the experimental $\mathrm{pED}_{50}$ of the test set compounds was 0.34 , and the correlation coefficient between experimental and predicted values is $\mathrm{R}^{2}=0.91$. The quite good predictive result indicates that the PCA model (7) is robust and not seriously over fitting for the training set. Of course, general trend should be Test $\mathrm{R}^{2}<\mathrm{XR}^{2}<\mathrm{R}^{2}$, the particularly high Test $\mathrm{R}^{2}$ should be attributed to chance correlation.

FIGURE10. Predicted $\mathrm{pED}_{50}$ values versus experimental $\mathrm{pED}_{50}$ values for 16 -compound test set of dataset 3

### 3.4 QSAR for dataset4

15 descriptors were selected through normal descriptor selection procedure. The statistical parameters of the model based on the 15 descriptors are: $\mathrm{R}^{2}=0.86, \mathrm{RMSE}=0.39, \mathrm{XR}^{2}=0.68$, XRMSE $=0.60, \mathrm{n}=42, \mathrm{~F}=10.54, \mathrm{~N}=15$. The names of the 15 descriptors are listed in Table 5 of supplementary materials. Principal component analysis was carried out on the 15 descriptors. 15 PCs are required to capture the $100 \%$ variance of the previous descriptor subset. The accumulative percentage of variance explained by the first five PCs is $83.58 \%$; with the $1^{\text {st }} \mathrm{PC}$ explaining $39.92 \%$, the $2^{\text {nd }} 18.85 \%, 3^{\text {rd }} 9.86 \%, 4^{\text {th }} 8.00 \%$, and $5^{\text {th }} 6.95 \%$. After stepwise selection, seven PCs (PC3, PC7, PC9, PC10, PC12, PC14, PC15) were selected to build the final model:

$$
\begin{align*}
& \mathrm{pED} 50=7.69+0.53 * \mathrm{PC} 3+0.15 * \mathrm{PC} 7+0.17 * \mathrm{PC} 9-0.35 * \mathrm{PC} 12-0.24 * \mathrm{PC} 14+0.24 * \\
& \mathrm{PC} 10+0.56 * \mathrm{PC} 15 \tag{8}
\end{align*}
$$

$$
\mathrm{R}^{2}=0.80, \mathrm{RMSE}=0.46, \mathrm{XR}^{2}=0.71, \mathrm{XRMSE}=0.57, \mathrm{n}=42, \mathrm{~F}=19.99
$$

The percentage of variance explained by the seven descriptors was listed in Table 6 respectively, along with the result of parameter effect test of model (8). The most interpretive PC of the model (8) is PC15 ( $\mathrm{F}=49.94$ ), which only explains $0.01 \%$ variance of original descriptor subset. The PCA procedure also succeeded in extracting useful information and getting rid of noisy information from original dataset.

Table 6. Effect Tests of the descriptors for model (8)

| Source | Correlation to $\mathrm{pED}_{50}$ | Sum of Squares | F Ratio | Prob > F | Percentage of variance (\%) |
| :---: | :---: | :---: | :---: | :---: | :---: |
| PC15 | 0.29 | 13.14 | 49.94 | $<.0001$ | 0.01 |
| PC3 | 0.25 | 11.59 | 44.08 | $<.0001$ | 9.86 |
| PC12 | 0.11 | 5.21 | 19.82 | $<.0001$ | 0.47 |
| PC14 | 0.05 | 2.35 | 8.95 | 0.0051 | 0.04 |
| PC10 | 0.05 | 2.32 | 8.84 | 0.0054 | 0.92 |
| PC9 | 0.03 | 1.22 | 4.66 | 0.0381 | 1.68 |
| PC7 | 0.02 | 0.95 | 3.63 | 0.0654 | 4.61 |

The leave-one-out cross-validated predictive $\mathrm{pED}_{50}$ values were listed in the Table 4 of supplementary materials and plotted in Figure 11.

FIGURE 11. Leave-one-out cross-validated prediction versus experimental $\mathrm{pED}_{50}$ values for dataset 4
A QSAR model with seven descriptive variables for a dataset of 42 compounds may have a tendency of over-fitting. The leave-four-out procedure was carried out to test the predictive ability
and robustness of the model. The predicted $\mathrm{pED}_{50}$ values for the 16 test compounds are listed in bold in Table 4 of supplementary materials and plotted in Figure 12. The RMSE between predicted $\mathrm{pED}_{50}$ and the experimental $\mathrm{pED}_{50}$ of the test set compounds was 0.65 , and the correlation coefficient between experimental and predicted values is $\mathrm{R}^{2}=0.71$.

FIGURE 12. Predicted $\mathrm{pED}_{50}$ values versus experimental $\mathrm{pED}_{50}$ values for 16 -compounds test set of dataset4

## 4 CONCLUSIONS

We have collected over 118 bisphosphonates with different bioactivities from various literature sources and performed QSAR studies on datasets according different bioactivities. For the GGPPSase inhibitor dataset (dataset1), we built a simple and explicit QSAR model based on the enzymatic activity of 28 compounds. This model has comparable predictive ability with that of the CoMFA model reported by Szabo et al. ${ }^{13}$ for the same dataset. The QSAR of Dataset 2 of 28 compounds with bioactivities against the growth of T. Brucei rhodesiense was studied using principal component analysis followed by stepwise vaiable selection. The PCA model based on the dataset also has nearly equal predictive ability with that of the CoMFA model built by Martin et al.. ${ }^{5}$ We divided the 86 bisphosphonates reportd by Novartis with in vivo activity data in TPTX rats into two sub datasets according their structural features and rough speculations of their mode of action. Robust PCA model was derived for each sub dataset. A leave-four-out test procedure shows that though the QSAR models based on in vivo bone resorption $\mathrm{pED}_{50}$ values cannot provide explicit indications for drug design, their predictive ability for related compounds is quite good.

## Appendix 1

Denotations of original descriptors adopted for PCA procedure in each dataset
I. Physical Properties that can be calculated from the connection table (with no dependence on conformation) of a molecule:

| Code | Description |
| :--- | :--- |
| apol | Sum of the atomic polarizabilities (including implicit hydrogens) with polarizabilities <br> taken from [CRC 1994]. |

II.Subdivided Surface Areas

The Subdivided Surface Areas are descriptors based on an approximate accessible van der Waals surface area calculation for each atom, $v_{i}$ along with some other atomic property, $p_{i}$. The $v_{i}$ are calculated using a connection table approximation. Each descriptor in a series is defined to be the sum of the $v_{i}$ over all atoms $i$ such that $p_{i}$ is in a specified range $(a, b]$.

In the descriptions to follow, $L_{i}$ denotes the contribution to $\log \mathrm{P}(\mathrm{o} / \mathrm{w})$ for atom $i$ as calculated in the SlogP descriptor [Crippen 1999]. $R_{i}$ denotes the contribution to Molar Refractivity for atom $i$ as calculated in the SMR descriptor [Crippen 1999]. The ranges were determined by percentile subdivision over a large collection of compounds.

| Code | Description |
| :--- | :--- |
| SlogP_VSA0 | Sum of $v_{i}$ such that $L_{i}<=-0.4$. |
| SlogP_VSA1 | Sum of $v_{i}$ such that $L_{i}$ is in $(-0.4,-0.2]$. |
| SlogP_VSA2 | Sum of $v_{i}$ such that $L_{i}$ is in $(-0.2,0]$. |
| SlogP_VSA3 | Sum of $v_{i}$ such that $L_{i}$ is in $(0,0.1]$. |
| SlogP_VSA4 | Sum of $v_{i}$ such that $L_{i}$ is in $(0.1,0.15]$. |
| SlogP_VSA5 | Sum of $v_{i}$ such that $L_{i}$ is in $(0.15,0.20]$. |
| SlogP_VSA6 | Sum of $v_{i}$ such that $L_{i}$ is in $(0.20,0.25]$. |
| SlogP_VSA7 | Sum of $v_{i}$ such that $L_{i}$ is in $(0.25,0.30]$. |
| SlogP_VSA8 | Sum of $v_{i}$ such that $L_{i}$ is in $(0.30,0.40]$. |
| SlogP_VSA9 | Sum of $v_{i}$ such that $L_{i}>0.40$. |

| SMR_VSA0 | Sum of $v_{i}$ such that $R_{i}$ is in $[0,0.11]$. |
| :--- | :--- |
| SMR_VSA1 | Sum of $v_{i}$ such that $R_{i}$ is in $(0.11,0.26]$. |
| SMR_VSA2 | Sum of $v_{i}$ such that $R_{i}$ is in $(0.26,0.35]$. |
| SMR_VSA3 | Sum of $v_{i}$ such that $R_{i}$ is in $(0.35,0.39]$. |
| SMR_VSA4 | Sum of $v_{i}$ such that $R_{i}$ is in $(0.39,0.44]$. |
| SMR_VSA5 | Sum of $v_{i}$ such that $R_{i}$ is in $(0.44,0.485]$. |
| SMR_VSA6 | Sum of $v_{i}$ such that $R_{i}$ is in $(0.485,0.56]$. |
| SMR_VSA7 | Sum of $v_{i}$ such that $R_{i}>0.56$. |

II. Atom Counts and Bond Counts and Kier\&Hall Connectivity and Kappa Shape Indices

| Code | Description |
| :--- | :--- |
| a_nH | Number of hydrogen atoms (including implicit hydrogens). This is calculated as the <br> sum of $h_{i}$ over all non-trivial atoms $i$ plus the number of non-trivial hydrogen atoms. |
| zagreb | Zagreb index: the sum of $d_{i}^{2}$ over all heavy atoms $i$. |
| KierFlex | Kier molecular flexibility index: (KierA1) (KierA2) / $n$ [Hall 1991]. |

## III. Adjacency and Distance Matrix Descriptors

| Code | Description |
| :--- | :---: |
| weinerPath | Wiener path number: half the sum of all the distance matrix entries as defined in <br> [Balaban 1979] and [Wiener 1947]. |
| weinerPol | Wiener polarity number: half the sum of all the distance matrix entries with a value of <br> 3 as defined in [Balaban 1979]. |

## IV. Pharmacophore Feature Descriptors

| Code | Description |
| :--- | :--- |
| vsa_don | Approximation to the sum of VDW surface areas of pure hydrogen bond donors (not <br> counting basic atoms and atoms that are both hydrogen bond donors and acceptors such <br> as -OH). |
| vsa_other | Approximation to the sum of VDW surface areas of atoms typed as "other". |

V. Partial Charge Descriptors (Let $q_{i}$ denote the partial charge of atom $i$ as defined above. Let $v_{i}$ be the van der Waals surface area of atom $i$.)

| Code | Description |
| :---: | :---: |
| $\begin{gathered} \text { Q_PC+ } \\ \text { PEOE_PC+ } \end{gathered}$ | Total positive partial charge: the sum of the positive $q_{i} . Q_{-} \mathrm{PC}+$ is identical to PC+ which has been retained for compatibility. |
| $\begin{gathered} \text { Q_PC- } \\ \text { PEOE_PC- } \end{gathered}$ | Total negative partial charge: the sum of the negative $q_{i}$. $Q_{-} \mathrm{PC}-$ is identical to $\mathrm{PC}-$ which has been retained for compatibility. |
| $\begin{gathered} \text { Q_RPC+ } \\ \text { PEOE_RPC+ } \end{gathered}$ | Relative positive partial charge: the largest positive $q_{i}$ divided by the sum of the positive $q_{i}$. Q_RPC+ is identical to RPC+ which has been retained for compatibility. |
| $\begin{gathered} \text { Q_PRC- } \\ \text { PEOE_RPC- } \end{gathered}$ | Relative negative partial charge: the smallest negative $q_{i}$ divided by the sum of the negative $q_{i}$. Q RPC- is identical to RPC- which has been retained for compatibility. |
| $\begin{gathered} \text { Q_VSA_POS } \\ \text { PEOE_VSA_POS } \end{gathered}$ | Total positive van der Waals surface area. This is the sum of the $v_{i}$ such that $q_{i}$ is nonnegative. The $v_{i}$ are calculated using a connection table approximation. |
| $\begin{gathered} \text { Q_VSA_NEG } \\ \text { PEOE_VSA_NEG } \end{gathered}$ | Total negative van der Waals surface area. This is the sum of the $v_{i}$ such that $q_{i}$ is negative. The $v_{i}$ are calculated using a connection table approximation. |

| $\begin{gathered} \text { Q_VSA_PPOS } \\ \text { PEOE_VSA_PPOS } \end{gathered}$ | Total positive polar van der Waals surface area. This is the sum of the $v_{i}$ such that $q_{i}$ is greater than 0.2 . The $v_{i}$ are calculated using a connection table approximation. |
| :---: | :---: |
| $\begin{gathered} \text { Q_VSA_PNEG } \\ \text { PEOE_VSA__PNEG } \end{gathered}$ | Total negative polar van der Waals surface area. This is the sum of the $v_{i}$ such that $q_{i}$ is less than -0.2 . The $v_{i}$ are calculated using a connection table approximation. |
| Q_VSA_HYD PEOE_VSA_HYD | Total hydrophobic van der Waals surface area. This is the sum of the $v_{i}$ such that $\left\|q_{i}\right\|$ is less than or equal to 0.2 . The $v_{i}$ are calculated using a connection table approximation. |
| Q_VSA_POL PEOE_VSA_POL | Total polar van der Waals surface area. This is the sum of the $v_{i}$ such that $\left\|q_{i}\right\|$ is greater than 0.2 . The $v_{i}$ are calculated using a connection table approximation. |
| $\begin{gathered} \text { Q_VSA_FPOS } \\ \text { PEOE_VSA_FPOS } \end{gathered}$ | Fractional positive van der Waals surface area. This is the sum of the $v_{i}$ such that $q_{i}$ is non-negative divided by the total surface area. The $v_{i}$ are calculated using a connection table approximation. |
| $\begin{gathered} \text { Q_VSA_FNEG } \\ \text { PEOE_VSA__FNEG } \end{gathered}$ | Fractional negative van der Waals surface area. This is the sum of the $v_{i}$ such that $q_{i}$ is negative divided by the total surface area. The $v_{i}$ are calculated using a connection table approximation. |
| Q VSA FPPOS PEOE_VSA_FPPOS | Fractional positive polar van der Waals surface area. This is the sum of the $v_{i}$ such that $q_{i}$ is greater than 0.2 divided by the total surface area. The $v_{i}$ are calculated using a connection table approximation. |
| Q VSA FPNEG PEOE_VSA_FPNEG | Fractional negative polar van der Waals surface area. This is the sum of the $v_{i}$ such that $q_{i}$ is less than -0.2 divided by the total surface area. The $v_{i}$ are calculated using a connection table approximation. |
| $\begin{gathered} \text { Q_VSA_FHYD } \\ \text { PEOE_VSA_FHYD } \end{gathered}$ | Fractional hydrophobic van der Waals surface area. This is the sum of the $v_{i}$ such that $\left\|q_{i}\right\|$ is less than or equal to 0.2 divided by the total surface area. The $v_{i}$ are calculated using a connection table approximation. |
| Q VSA FPOL PEOE_VSA_FPOL | Fractional polar van der Waals surface area. This is the sum of the $v_{i}$ such that $\left\|q_{i}\right\|$ is greater than 0.2 divided by the total surface area. The $v_{i}$ are calculated using a connection table approximation. |
| PEOE_VSA+6 | Sum of $v_{i}$ where $q_{i}$ is greater than 0.3 |
| PEOE_VSA+5 | Sum of $v_{i}$ where $q_{i}$ is in the range $[0.25,0.30)$. |
| PEOE_VSA+4 | Sum of $v_{i}$ where $q_{i}$ is in the range $[0.20,0.25)$. |
| PEOE_VSA+3 | Sum of $v_{i}$ where $q_{i}$ is in the range $[0.15,0.20)$. |
| PEOE_VSA+2 | Sum of $v_{i}$ where $q_{i}$ is in the range $[0.10,0.15)$. |
| PEOE_VSA+1 | Sum of $v_{i}$ where $q_{i}$ is in the range $[0.05,0.10)$. |
| PEOE_VSA+0 | Sum of $v_{i}$ where $q_{i}$ is in the range $[0.00,0.05)$. |
| PEOE_VSA-0 | Sum of $v_{i}$ where $q_{i}$ is in the range $[-0.05,0.00)$. |
| PEOE_VSA-1 | Sum of $v_{i}$ where $q_{i}$ is in the range [ $-0.10,-0.05$ ). |
| PEOE_VSA-2 | Sum of $v_{i}$ where $q_{i}$ is in the range $[-0.15,-0.10)$. |
| PEOE_VSA-3 | Sum of $v_{i}$ where $q_{i}$ is in the range [ $-0.20,-0.15$ ). |
| PEOE_VSA-4 | Sum of $v_{i}$ where $q_{i}$ is in the range $[-0.25,-0.20)$. |
| PEOE_VSA-5 | Sum of $v_{i}$ where $q_{i}$ is in the range [ $-0.30,-0.25$ ). |
| PEOE_VSA-6 | Sum of $v_{i}$ where $q_{i}$ is less than -0.30 . |

## VI. Potential Energy Descriptors

## Code

Description

| E_ang | Angle bend potential energy. In the Potential Setup panel, the term enable flag is <br> ignored, but the term weight is applied. |
| :---: | :---: |
| E_sol | Solvation energy. In the Potential Setup panel, the term enable flag is ignored, but the <br> term weight is applied. |
| E_stb | Bond stretch-bend cross-term potential energy. In the Potential Setup panel, the term <br> enable flag is ignored, but the term weight is applied. |
| E_strain | Local strain energy: the current energy minus the value of the energy at a near local <br> minimum. The current energy is calculated as for the E descriptor. The local minimum <br> energy is the value of the E descriptor after first performing an energy minimization. <br> Current chirality is preserved and charges are left undisturbed during minimization. The <br> structure in the database is not modified (results of the minimization are discarded). |
| E_tor | Torsion (proper and improper) potential energy. In the Potential Setup panel, the term <br> enable flag is ignored, but the term weight is applied. |
| E_vdw | van der Waals component of the potential energy. In the Potential Setup panel, the <br> term enable flag is ignored, but the term weight is applied. |

VII. Surface Area, Volume and Shape Descriptors

| Code | Description |
| :--- | :--- |
| ASA | Water accessible surface area calculated using a radius of 1.4 A for the water <br> molecule. A polyhedral representation is used for each atom in calculating the surface <br> area. |
| Vol | van der Waals volume calculated using a grid approximation (spacing 0.75 A ). <br> VSAvan der Waals surface area. A polyhedral representation is used for each atom in <br> calculating the surface area. |

VII. Conformation Dependent Charge Descriptors

| Code | Description |
| :--- | :--- |
| ASA + | Water accessible surface area of all atoms with positive partial charge (strictly greater <br> than 0$).$ |
| ASA_H | Water accessible surface area of all hydrophobic $\left(\left\|q_{i}\right\|<0.2\right)$ atoms. |
| DASA | Absolute value of the difference between ASA+ and ASA-. |
| DCASA | Absolute value of the difference between CASA+ and CASA- [Stanton 1990]. |

[^0]:    Abbreviations and notations
    $\mathrm{ED}_{50}$, the dose of compound administratered sc, which results in a $50 \%$ reduction of the hypercalcemia induced in TPTX rats by 1,25-dihydroxyvitamin $\mathrm{D}_{3}$ $\mathrm{pED}_{50}$ or $\mathrm{pIC}_{50}$, negative logarithmic value of $\mathrm{ED}_{50} / \mathrm{IC}_{50}$ PCA, principal component analysis
    Bps, bisphosphonates
    FPPSase, farnesyl pyrophosphate synthase
    $R^{2}$, correlation coefficient
    $\mathrm{IC}_{50}$, experimental concentration required to reduce activity/proliferation of enzymes/cells/parasites by $50 \%$

    TPTX, thyroparathyroidectomy
    QSAR, quantitative structure-activity relationships
    GGPPSase, geranylgeranyl diphosphate synthase
    RMSE, root mean square error
    XRMSE, leave-one-out cross validated root mean square error
    XPRED, leave-one-out cross validated prediction

[^2]:    $a$ : the dose of compound administratered sc, which results in a $50 \%$ reduction of the hypercalcemia induced in TPTX rats by 1,25 -dihydroxyvitamin $\mathrm{D}_{3} .{ }^{14} \mathrm{~b}$ : experimental concentration required to reduce proliferation of T . Brucei rhodesiense by $50 \% .^{4,5} c$ : experimental concentration required to reduce activity of GGPPSase by $50 \% .{ }^{13}$

    Datasetl are made up of 28 BPs with $\mathrm{IC}_{50}$ values against GGPPSase. The library covers many diverse structural features: ionic bisphosphonate and diphosphate groups; alkyl, alkenyl (prenyl), aryl, and heteroaryl side chains; 1-OH- and 1-H-bearing bisphosphonates; and nitrogen-containing
